## **Fall Armyworm Notice: After Planting, Watch Your Wheat!**

Tom A. Royer, Extension Entomologist

I am beginning to get reports of fall armyworm caterpillars “loitering around” in bermudagrass and fescue pastures and roadside ditches. As wheat planting begins, producers should check fields regularly after seedling emergence. Fall armyworm moth flight will continue into fall. Scout for fall armyworms by examining plants in several (5 or more) locations in the field. They are most active in the morning or late afternoon.

Look for “window paned” leaves and count all sizes of larvae. Examine plants along the field margin as well as in the interior, because they sometimes move in from road ditches and weedy areas. The suggested treatment threshold is 2-3 larvae per linear foot of row in wheat with active feeding. Producers have a wide choice of registered insecticides, but application timing is important because small caterpillars are much more susceptible to control. We won’t get relief from fall armyworms until we get a killing frost, so keep vigilant!

Consult the newly updated OSU Fact Sheets [CR-7194 Management of Insect and Mite Pests of Small Grains](#) for control suggestions.

## Sorghum Insects: Chinch Bug and Corn Leaf Aphids are Plentiful!

Tom A. Royer, Extension Entomologist

Sorghum producers were careful in selecting sorghum hybrids to grow that have resistance to sugarcane aphid. They have also been vigilant in scouting their fields for buildup of sugarcane aphids this year. Their reward has been lower numbers of sugarcane aphids being present in their fields, and fewer acres needing treatment. However, this summer has been one for the books with regard to chinch bugs and corn leaf aphids. Both have been very active in sorghum this year.

Chinch bugs are noticeably active and they are causing some injury to sorghum plants. Unfortunately, their habits make them very difficult to control. They prefer to live at the base of the plant and lay eggs behind the lower leaf sheaths. Upon hatching, nymphs live in the space between the stalk and the leaf collar.

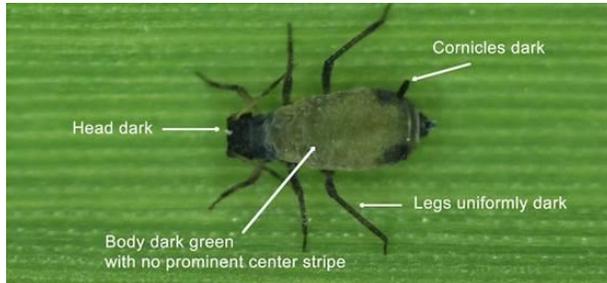

I have been asked, “Why do we have so many chinch bugs in sorghum this late in the year?” My best answer is that they are simply increasing because Mother Nature provided optimal conditions for them to reproduce without their normal population “checks” which includes the fungal pathogen *Beauveria bassiana*. We typically population numbers cycle over a 7-10 year period.

Chinch bug management is difficult under any circumstance. Insecticide control on mature plants is often ineffective. Why? For two reasons: the spray is difficult to cover the lower parts of the plant, and most insecticide active ingredients do not move through the leaf tissue, so the nymphs can avoid exposure to the insecticide. If close to harvest, do so as soon as possible, because chinch bug feeding can weaken stalks, making them more prone to lodging. For late-planted sorghum intended for a dual crop, insecticide treatment is suggested when chinch bug numbers reach 50 per plant. Apply registered insecticides at the full-recommended rate, delivered in at least 20 gallons of water per acre. Use either cone nozzles designed to provide high pressure for canopy penetration or through double-swivel drop nozzles targeted to the base of the plant. Morning applications are most effective because that is when the bugs are more exposed. Check OSU Current Report [CR-7170 Management of Insect and Mite Pests of Sorghum](#) for suggested insecticides.

## What about Corn Leaf Aphid?

Corn leaf aphids are also very prevalent in sorghum, usually in the whorl. They can build into large numbers, and they produce honeydew. Control of corn leaf aphids seldom is justified. While they can “make a mess” in a sorghum whorl, research out of Texas suggests that they rarely cause significant yield loss and they serve as a great source of food to attract natural enemies such as lady beetles, lacewings, syrphid larvae and parasitic wasps.

Corn leaf aphid

Typical corn leaf infestation

Syrphid larva

Lady beetle larva

Lacewing larva
